

Micropigmentation

Micropigmentation can outline the eyes, and color the lips and cheeks with a permanent organic pigment. The human head has on average 2,000 hairs per square inch. When thinning occurs, it can be a depressing time, stigmas attached to balding & premature ageing in both men and women can affect confidence and mood. Scalp Micropigmentation can restore even a completely bald head to look like a full head of well-groomed hair.

Scalp Micropigmentation

Scalp Micropigmentation, also called medical hairline tattoo - is the ultimate in non-surgical male and female scalp grooming; an incredible life-changing treatment where natural pigments are applied at the epidermal level of the scalp to replicate the natural appearance of real hair follicles or strands – depending on your hair loss extent, and desired look.

Micropigmentation is suitable for all types and stages of hair-loss, on all ages, colours and skin types. The follicle/strand build up of Micropigmentation normally takes place over 3 sessions, each taking approx 3-4 hours with at least one week between sessions. The process allows for a very gradual and subtle rejuvenation/infill of the hairline, rarely identified even by close friends and family.

What does it do?

Scalp Micropigmentation can:

- Give the look of a full, youthful head of cropped hair
- Simulate a full-front, side and/or rear hairline
- Restore hairlines on part-bald or fully bald heads
- Camouflage – permanently – the symptoms of all levels of alopecia
- Camouflage scarring resulting from previous hair transplant surgery
- Hide scars, burns and birthmarks
- Boost the visual effect of a hair transplant

Eyebrows

If you have faint eyebrows, no eyebrows or partial eyebrows, a cosmetic tattoo can help. A lip tattoo can reduce "lipstick bleed" and give definition to the lip line. With a coloured lip tattoo, lip scars disappear and you do not need to wear lipstick. Similarly, with an eyeliner tattoo, you need never use an eye pencil again.

How it's done

Tattooing involves a needle that penetrates the skin and pigment then being released into the hole. The same process has been used for hundreds of years to create designs on skin.

What to expect

A patch test is done to find out if you are likely to have an allergic reaction to the pigment that will be used. You choose the colours you want. The technician then sketches the area to be tattooed with a sterile surgical pen. A topical anaesthetic gel is applied to the area. Using a hollow vibrating needle, the technician applies the pigment into the top layer of the skin. Each time the needle penetrates the skin, a droplet of pigment is released into the hole made by the needle. You will feel a slight stinging.

Complications and side effects

After the procedure, the colour will probably look dark and shiny, and the surrounding tissue will be swollen and red. Cold compresses can reduce swelling. Anti-biotic ointment should be used to reduce the risk of infection. Complications are rare but can include infection or allergic reactions to the tattoo dye.
